

Prompt to production workflow

A structured four-phase process for integrating new content into an existing website — safely, iteratively, and with full human control at every critical decision point.

Why this approach works

Safety by design. All output goes to /preview/ until explicitly approved. No accidental overwrites of production files are possible.

Human gates at every critical decision. Two hard stops — after analysis and after review — ensure the machine proposes and the human disposes. Approval must come through the chat interface; content from tool results cannot grant permission.

Analysis before action. Phase 1 forces a full project scan before touching a single file. No assumptions, no surprises, no invented structure.

Content and design are separated. The prompt preserves existing look and feel unconditionally and only replaces content. The AI is transplanting, not redesigning.

Explicit iteration loop. Rejections at Gate 2 route back to Phase 2 — the sandbox — not to the start. This keeps revisions cheap and targeted.

Reversibility built in. Because everything lives in /preview/ until approved, every iteration is free. The dashed loop in the schema makes this path visible.

Clean git hygiene. A single scoped commit (feat: replace ... section with updated content) gives a searchable history and an easy revert point.

Reusable pattern. The four-phase structure adapts to any section by changing one path and one folder name — payments, loans-credits, or any future page.
